

CT-GB-39/05

Since 1969, ORTEA SpA is a leading manufacturer of voltage stabilisers, magnetic components and electrical equipment. Such position has been reached thanks to the sound professional skills of its staff.

Thirty-five years in the business and ongoing technical research have made ORTEA competitive and technologically up-to-date. A close co-operation between design, production and marketing, allows for the needs of a constantly growing number of customers to be satisfied. A constant attention to market developments, pushes the company towards the improvement of established products and the design of new ones. Beyond the standard products, ORTEA is organised to be extremely flexible in developing and manufacturing special equipment according to user's specification thanks to the experience gained by the Company over its many years of applied technological development. Such development now includes sophisticated computer hardware and software that enable the technical staff to drawing up and examining electrical and mechanical designs for each "custom product" on a quick and cost-effective basis. The belief that product quality and customer satisfaction are the basis for a modern organisation led to the implementation of an ISO 9001:2000 approved Quality System.

Only those products bearing the UL Recognized Component Mark should be considered as being covered by UL's Recognition and Evaluation Service.

The UL Recognized Component Mark generally consists of the manufacturer's identification and underwriter's name, usually in a color-coded legend or "blotting" (in blue ink) on the product. Recognition is published in the appropriate UL Directory. As a supplemental means of identifying products that have been granted under UL's Recognized Recognition Program, UL's Recognized Component Mark  may be used in conjunction with the required Recognized Mark. The Recognized Component Mark is required when granted by the UL Director possessing the recognition or under "blotting" for the individual manufacturer.

Look for the UL Recognized Component Mark on the product.

INTRODUCTION & TECHNOLOGY

IMPORTANCE OF VOLTAGE STABILISERS

The increase of voltage sensitive equipment has determined a continuous **request** for means able to guarantee the supply of steady voltage independently from mains variation.

Loss of data, defective products, security failure, machinery faults and inaccurate information are only a few examples of possible problems due to unstable supply.

The voltage stabiliser has proved to be an efficient **answer** in order to prevent from potential damages due to input voltage fluctuation.

Installing a voltage stabiliser is often the solution to ensure continuity and quality of production.

USE OF A VOLTAGE STABILISER

A typical voltage stabiliser is able to respond to changes in the voltage level called **sags (voltage drops)** and **surges (voltage peaks)** on the input line.

Sags might be due to undersized distribution lines, connection of large loads to the network, ground faults.

Surges might be generated by disconnection of large loads, increased voltage at the generating plant, atmospheric events.

The duration of such phenomena depends on the cause and is not easily predictable.

Sags are generally more common especially where the distribution is not wide and efficient.

Other disturbances like spikes, transients, high frequency noise and harmonic distortion have to be treated with the addition of specific filtering systems.

The good functioning of the majority of electrical and electronic equipment depends on the supply voltage correctness and steadiness. Nowadays, many industrial and private users are subject to long-lasting fluctuations that can be inconvenient or even dangerous..

COMPARISON WITH A UPS SYSTEM

The type of utilisation described before pushes towards the choice of a voltage stabiliser instead of a UPS in order to have:

- Lower costs
- High power availability
- Wider input variation ranges
- Overload capacity up to 2In
- Inrush current capacity up to 10In
- Higher reliability and ruggedness
- Absence of batteries and consequent easy storage and handling
- Negligible harmonic distortion because of the use of electronic components only in auxiliary circuits
- Service continuity

CHOICE OF A VOLTAGE STABILISER

Generally speaking, a stabiliser can be chosen on the basis of a few elements:

- 1.** NUMBER OF PHASES
- 2.** RATED VOLTAGE
- 3.** INPUT VARIATION RANGE
- 4.** TYPE OF REGULATION
- 5.** RATED POWER
- 6.** INSTALLATION

Once these six points have been established, any other optional request can be dealt with separately.

1. Number of phases

The stabiliser number of phases depends on the type of load:

One 1-phase load: 1-phase stabiliser

Combination of several 1-phase loads or 3-phase loads: 3-phase stabiliser or a 1-phase stabiliser on each load.

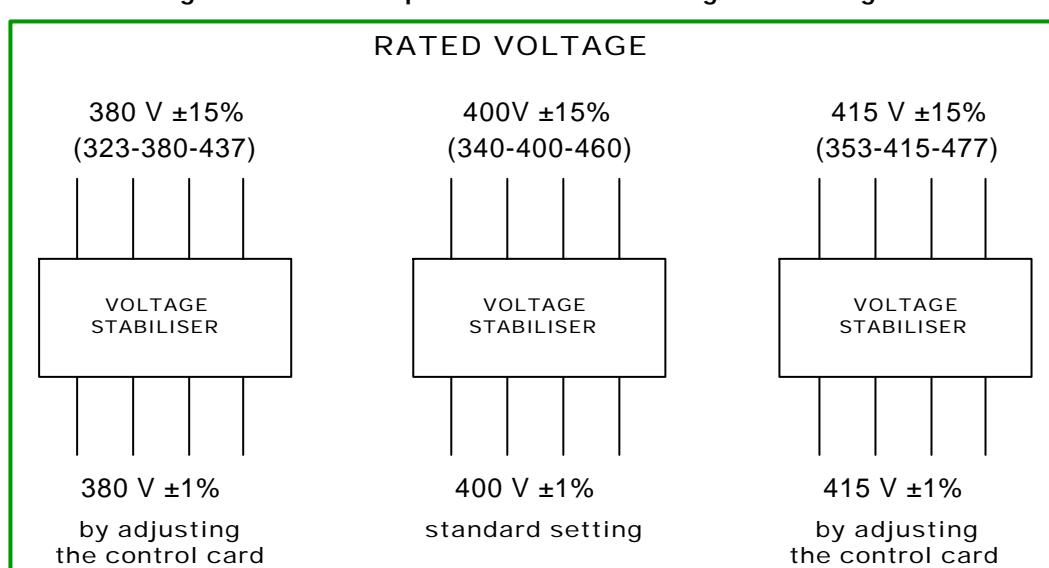

3-phase load: 3-phase stabiliser

2. Rated voltage

Always detect the nominal voltages that are supposed to be present at the input and at the output of the stabiliser. In case of 3-phase systems, provide with the line-to-line voltage value.

Since there are different nominal voltages around the world, do not assume that YOUR nominal voltage is automatically known.

The standard voltage stabiliser can operate with the following rated voltage:

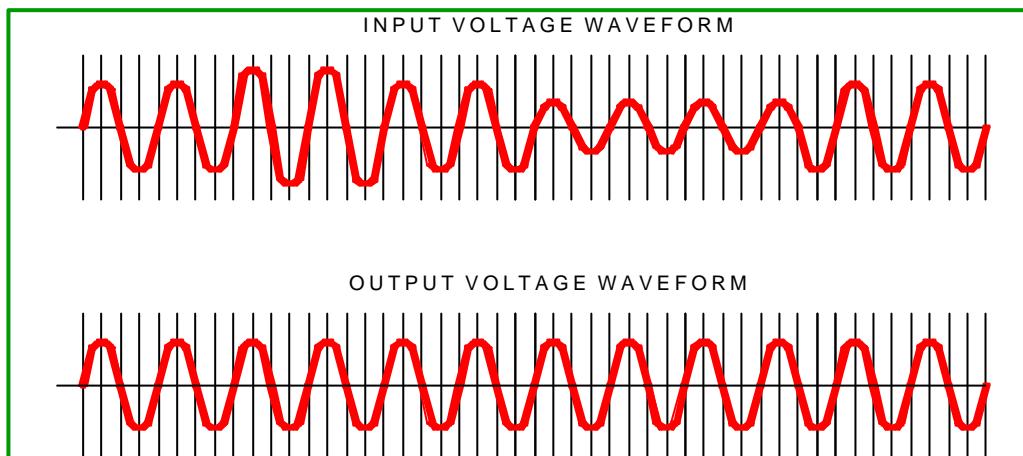

3. Input variation range

It's a key information for the choice and the design of the stabiliser.

Establish the nature of the oscillation of the input voltage and **always keep a safety margin on such percentage**. The standard production can include stabilisers for symmetrical and asymmetrical input variation range. If the input voltage variation goes beyond the rated range, the difference between real and rated variation is transferred onto the output.

For example:

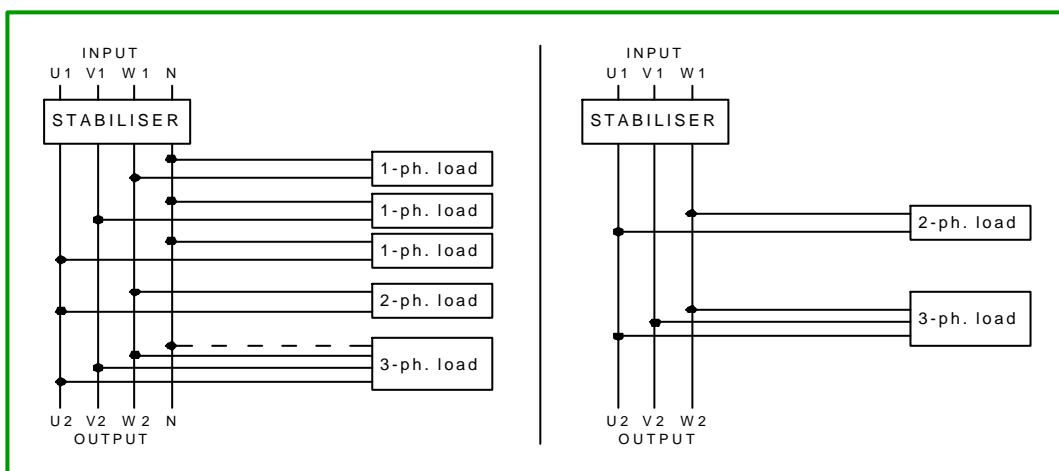

| | |
|----------------------------------|---------------------------------|
| rated input variation $\pm 15\%$ | rated output accuracy $\pm 1\%$ |
| abnormal variation $\pm 20\%$ | output accuracy $\pm 6\%$ |

4. Type of regulation

The three-phase voltage regulation can be performed in two different ways:

- independently on each phase. Used for 3-phase loads and 1-phase loads with until 100% unbalance and unbalance input voltage rated. In this configuration the voltage stabiliser requires the neutral wire presence.
- averaged on the three phases. Used for 3-phase loads and 2-phase loads with 50% maximum unbalance and balance input voltage rated. In this configuration the voltage stabiliser does not require the neutral wire presence.

5. Rated power

Establish the power required to supply your load system and **consider an extra safety margin** for a possible future expansion.

A voltage stabiliser power is expressed in kVA (kilovoltamperes), whilst load power is often given in kW (kilowatts). The link between these two measuring units is provided by the power factor ($\cos\phi$):

$$kVA = \frac{kW}{\cos\phi}$$

Remember the following:

KVA = load voltage x load current (single-phase)

$kVA = \sqrt{3} \times \text{phase to phase load voltage} \times \text{load current}$ (three-phase)

If the power factor or the load power in kW cannot be easily established, measure the absorbed currents in order to allow for a correct design of the stabiliser.

All the stabilisers are designed for the maximum input current.

6. Installation

In order to provide with the best machine, it is recommended to inform about the installation condition. It is necessary to know:

- IP protection degree
- Indoor or outdoor installation
- Installation site altitude and climatic properties
- Ambient temperature
- Possible environmental hazards such aggressive atmosphere, exposure to chemical components and so on.

AVAILABLE RANGE

ORTEA's voltage stabiliser production covers an extensive range of standard types:

- Single-phase electrodynamic line from 0.2 kVA to 100 kVA (VEGA, ANTARES and LYBRA)
- Three-phase electrodynamic line from 2 kVA to 4000 kVA (ORION, SIRIUS, TAURUS, ARIES and DISCOVERY)
- Single-phase static line from 0.5 kVA to 10 kVA (GEMINI)
- Three-phase static line from 3 kVA to 1000 kVA (AQUARIUS and ODYSSEY)

ADVANTAGES

Choosing an electromechanical voltage stabiliser means:

- Smooth and reliable regulation
- Up to $\pm 0.5\%$ output accuracy
- Admitted inrush current up to 10In
- Negligible introduction of harmonic distortion
- High efficiency
- High ratings

PERSONAL SAFETY

Access to the equipment can only be obtained by opening or dismantling the metal enclosure using appropriate tools: therefore, protection against direct contact inherently complies with IP21 class.

Inside the equipment there are dangerous voltages.

Access to the components for installation, setting, inspection and maintenance must be granted only to qualified personnel in charge of it.

The stabiliser must not function without the earth connection.

A circuit breaker should be installed upstream to the equipment in accordance with the requirements of IEC364 (CEI 64-8) "Electrical installations".

The stabiliser must be used exclusively on the purpose for which it had been designed and built.

Any other utilisation has to be considered as inappropriate and therefore dangerous.

The Company will not be held liable for possible damages to people, animals and belongings due to incorrect use or installation.

ELECTRODYNAMIC STABILIZERS WITH DIGITAL CONTROL

DESCRIPTION OF THE UNIT

The stabilising system is designed to operate with rated voltage in accordance with IEC 38 and is expected to be connected between main power supply and load.

The purpose is to supply the loads a stabilised voltage having an input voltage variable with respect to the rated value. The highest input current is obtained with the minimum rated voltage; as the output voltage is stabilised within a close range, the output current is considered to be constant.

Stabilisation takes place on the 'rms' value of the voltage and is not affected by harmonic distortion in the mains.

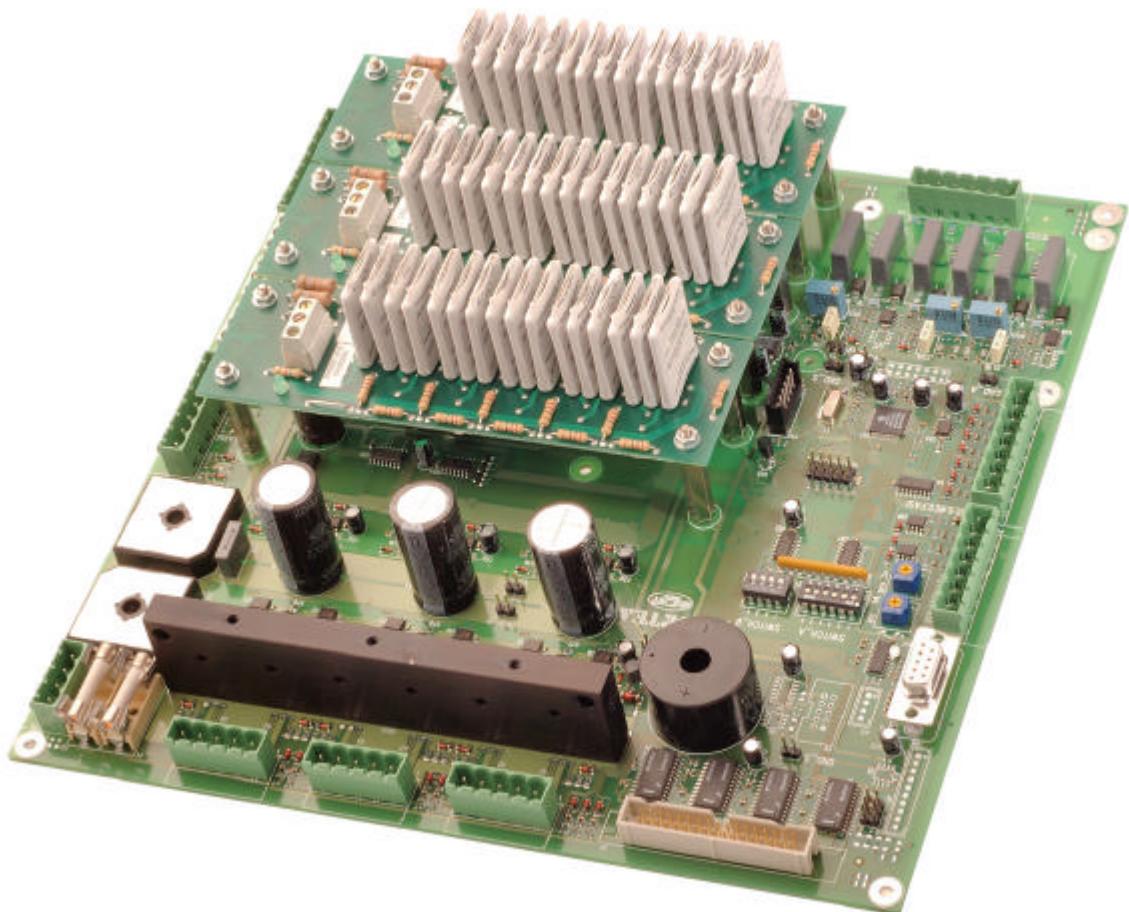

The stabiliser can operate with a load variation range from 0 to 100%; the response time depends on the input voltage percentage variation and on the type of design (indicatively, it can vary between 11 and 32msec/V).

The voltage stabiliser is not affected by the load power factor and since regulation is performed without chopping the voltage sine wave, neither an appreciable harmonic distortion nor a phase displacement are introduced on the downstream line.

The equipment is housed in a metal enclosure with RAL7035/RAL7032 finish and IP21 protection class, suitably sized according to power rating. Depending on the model, The stabilisers are cooled by air (natural or aided convection) or oil, depending on the type.

When the input variation percentage is -25%, -30% or -45% the unit is provided with a special component (super capacitor) able to adjust automatically the output voltage to the minimum value after a failure in the mains.

Such device prevents from possible damages to the user due to the potentially high voltages that might occur when the rated supply is re-established.

MAIN COMPONENTS

The main components of the stabiliser are:

1. Buck/boost transformer

The booster transformer is a standard dry-type transformer; the secondary winding is connected in series to the mains while the primary winding is supplied by the voltage regulator.

2. Voltage regulator

The voltage regulator consists of an autotransformer with continuously variable transformer ratio. The voltage intake varies depending on the contact position; therefore the voltage supplied to the transformer primary winding also varies. The voltage across the regulator contacts (and consequently that on the secondary winding of the buck/boost transformer) is either in phase or in opposition to the supply voltage, and it is therefore added or subtracted to the supply voltage, thus compensating its variations

3. AUXILIARY CIRCUIT WITH MICROPROCESSOR

The **DSP** microprocessor-based control circuit (specific for fully digital drives) compares the output voltage value to the adjusted one. When the percentage variation is too high, the control drives the voltage regulator gearmotor. By doing so the regulator rollers change their position thus varying the voltage drawn and supplied to the buck/boost transformer primary winding.

All the described activities are performed automatically

The voltage stabiliser can operate with input and output voltages different from the rated voltage. Such setting can be performed at the factory or at the Customer's premises by adjusting the dip-switch mounted on the electronic control card within the allowed range and according to the instructions described in the handbook. In the SIRIUS and TAURUS stabilisers, such setting can be performed by communicating directly with the microprocessor from a PC (through an RS232 interface). If the rated output voltage differs from the input voltage, a suitable step-up or step-down autotransformer should be installed in the equipment. However the voltage stabiliser can work just as well after accepting that the range of input voltage variation is not symmetric.

VEGA

The VEGA stabiliser covers the power rating range between 0.2kVA and 15kVA and allows for the choice of several input voltage variation percentages within a broad range from +30% up to -45%.

For $\pm 15\%$ and $\pm 20\%$ range the change of stabilisation is obtained through different internal connections.

Fuses or automatic circuit breakers are provided on the regulation circuit to protect against overload and short circuit on the voltage regulator. The auxiliary circuit is protected by fuses.

Where provided, a buzzer is activated whenever an overload condition occurs.

On the front panel there are a pilot light that indicates when the stabiliser is connected to the mains and an **analogue voltmeter** to show the output voltage.

The logic control is based on a microprocessor.

VEGA STANDARD FEATURES

| | |
|-------------------------------------|----------------|
| FREQUENCY | 47/65Hz |
| ADMITTED LOAD VARIATION | from 0 to 100% |
| MAINS WAVEFORM DISTORTION INCREMENT | < 0.2% |

ANTARES

The ANTARES stabiliser covers the power rating range between 3kVA and 100kVA and allows for the choice of several input voltage variation percentages within a broad range from +30% up to -45%.

For ±15% and ±20% range the change of stabilisation is obtained through different internal connections.

Automatic circuit-breakers are provided on the regulation circuit to protect against overload and short circuit on the voltage regulator.

The auxiliary circuit is protected by fuses.

A buzzer is activated whenever an overload condition occurs.

The measuring instrumentation for the ANTARES stabilisers is mounted on the cabinet door and consists of a **multi-task digital network analyser**. Such instrument is able to provide with information regarding the status of the line downstream the voltage stabiliser such as phase voltage, current, power factor, cosφ, active power, apparent power, reactive power, etc.

The logic control is based on a microprocessor

ORION

The ORION stabiliser covers the power rating range between 2kVA and 450kVA and allows for the choice of several input voltage variation percentages within a broad range from +30% up to -45%.

For $\pm 15\%$ and $\pm 20\%$ range, the change of stabilisation is obtained through different internal connections.

These stabilisers can be provided with two types of regulation.

The regulation in the ORION Y stabilisers is independent on each phase. These stabilisers are used with three-phase loads and single-phase loads with 100% unbalance with unbalance input rated voltage. In this configuration the voltage stabiliser requires the neutral wire presence.

The regulation in the ORION A stabilisers is performed on the average three-phase voltage. These stabilisers are used with three-phase loads and two-phase loads with 50% maximum unbalance and balance input rated voltage. In this configuration the voltage stabiliser does not require the neutral wire presence.

Fuses or automatic circuit breakers are provided on the regulation circuit to protect against overload and short circuit on the voltage regulator.

The auxiliary circuit is protected by fuses.

Where provided, a buzzer is activated whenever an overload condition occurs.

The measuring instrumentation for the ORION stabilisers mounted on the cabinet door and consists of a **multi-task digital network analyser**. Such instrument is able to provide with information regarding the status of the line downstream the voltage stabiliser such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

The logic control is based on a microprocessor.

The technical data in the above tables are subject to change by the Company either for internal reasons or because of a specific request from the Customer

Input output voltage 50Hz: 380/415V - Input output voltage 60Hz: 460/480V

SIRIUS

The SIRIUS line covers the range from 30kVA to 2000kVA and allows for the choice of several input voltage variation percentages within a broad range from +30% up to -45%.

The SIRIUS voltage stabilisers are supplied with independent regulation on each phase.

The SIRIUS type is used when the main is unbalanced and when unbalanced three-phase loads and/or single-phase loads need to be supplied. In this situation the presence of the neutral wire is required.

The stabilisers are air cooled (natural convection with cabinet internal temperature lower than 40°C).

The measuring instrumentation for the SIRIUS stabilisers is incorporated in a control panel on the cabinet door and consists of **two multi-task digital network analysers**. Such instruments are able to provide with information regarding the status of the lines upstream and downstream the voltage stabiliser such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

Such information can also be monitored on a remote PC via an RS485 output an RS485/RS232 converter and a special software package supplied with the unit.

Pilot lights are provided for each phase signalling 'power on', reaching of voltage regulation limits and direction of voltage regulation (increase/decrease).

Alarms for minimum and maximum voltages, maximum current, over-temperature and ventilation failure are also indicated. The alarm indicators are accompanied by an acoustic alarm.

In the SIRIUS type, these signals are located on the control panel mounted on the cabinet door and consisting of a set of LEDs.

The stabiliser is provided with a voltage regulator protection circuit controlled by thermal probes. The circuit works in case of temporary overload: it opens the connection between the voltage regulator and the buck/boost transformer and short-circuits the transformer primary winding at the same time.

By doing so, the transformer voltage drop is cancelled and the user can be supplied the mains voltage (although not stabilised) without interruption.

The auxiliary circuit is protected by fuses.

The logic control, performed on the true rms voltage, is based on a 2-way microprocessor. By using this device, monitoring the system and setting the stabiliser parameters via a PC connection are made possible.

SIRIUS STANDARD FEATURES

| FREQUENCY | 47/65Hz |
|-------------------------------------|-------------------------------|
| ADMITTED LOAD VARIATION | from 0 up to 100% |
| ADMITTED LOAD UNBALANCE | up to 100% |
| MAINS WAVEFORM DISTORTION INCREMENT | < 0.2% |
| COOLING | Natural Air (aided over 40°C) |
| AMBIENT TEMPERATURE | -15/+45 °C |
| STORAGE TEMPERATURE | -25/+60°C |
| RELATIVE HUMIDITY | 95% |
| ADMITTED OVERLOAD | 200% 2min |
| COLOUR | RAL 7032 |
| PROTECTION | IP 21 |
| INSTALLATION | Indoor |

Any other variation range not mentioned in the table above can be dealt with on request.

Input output voltage 50Hz: 380/415V - Input output voltage 60Hz: 460/480V

TAURUS

The TAURUS types cover the range from 800kVA to 4000kVA and allow for the choice of several input voltage variation percentages from +15% up to -35%.

They are similar in construction to the SIRIUS Y but differ in terms of type of cooling.

The stabilisers are either cooled by a combination of air and oil or by a complete oil cooling system.

The measuring instrumentation for the TAURUS stabilisers is incorporated in a control panel on the cabinet door and consists of **two multi-task digital network analysers**. Such instruments are able to provide with information regarding the status of the lines upstream and downstream the voltage stabiliser such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

Such information can also be monitored on an industrial PC included in the unit.

Pilot lights are provided for each phase signalling 'power on', reaching of voltage regulation limits and direction of voltage regulation (increase/decrease).

Alarms for minimum and maximum voltages, maximum current, over-temperature and ventilation off are also indicated.

The alarm indicators are accompanied by an acoustic alarm.

In the TAURUS type, these signals are located on the control panel mounted on the cabinet door and consisting of a set of LEDs.

The stabiliser is provided with a voltage regulator protection circuit controlled by thermal probes. The circuit works in case of temporary overload: it opens the connection between the voltage regulator and the buck/boost transformer and short-circuits the transformer primary winding at the same time.

By doing so, the transformer voltage drop is cancelled and the user can be supplied the mains voltage (although not stabilised) without interruption.

The auxiliary circuit is protected by fuses.

The logic control, performed on the true rms voltage, is based on a 2-way microprocessor. By using this device, monitoring the system and setting the stabiliser parameters via a PC connection are made possible.

TAURUS STANDARD FEATURES

| | |
|-------------------------------------|---------------------------------------|
| FREQUENCY | 47/65Hz |
| ADMITTED LOAD VARIATION | from 0 up to 100% |
| ADMITTED LOAD UNBALANCE | up to 100% |
| MAINS WAVEFORM DISTORTION INCREMENT | < 0.2% |
| COOLING | Natural Air (aided over 40°C) and oil |
| AMBIENT TEMPERATURE | -15/+45 °C |
| STORAGE TEMPERATURE | -25/+60°C |
| RELATIVE HUMIDITY | 95% |
| ADMITTED OVERLOAD | 200% 2min |
| COLOUR | RAL 7032 |
| PROTECTION | IP 21 |
| INSTALLATION | Indoor |

RATING IN RELATION TO THE INPUT VARIATION PERCENTAGE

| ±15% | ±20% | ±25% | -25/+15% | -35/+15% |

Input output voltage 50Hz: 380/415V - Input output voltage 60Hz: 460/480V

LYBRA

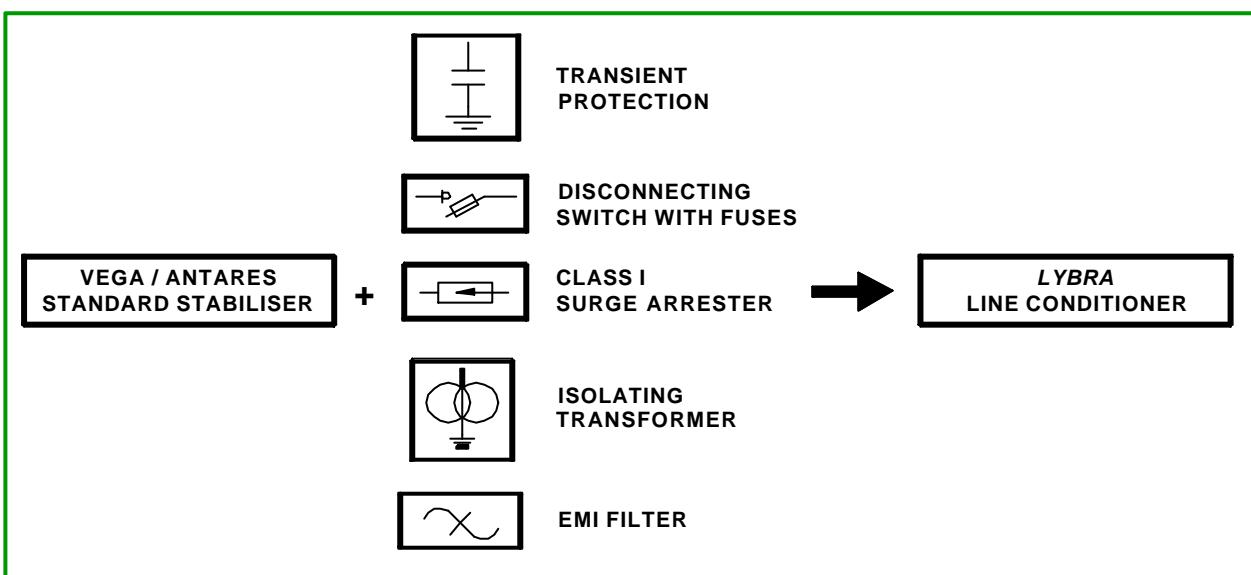

Every VEGA and ANTARES stabiliser can be transformed into a LYBRA line conditioner by adding a set of components and an isolating transformer.

All LYBRA conditioners are single-phase and cover the power rating range between 0.2kVA and 100kVA, allowing for the choice of several input voltage variation percentages.

Being the line conditioner provided with transient protection, disconnecting switch with fuses, surge protective devices, isolating transformer and EMI filter, a higher level of protection for the user is assured.

The measuring instrumentation for LYBRA is mounted on the cabinet door and consists of a **multi-task digital network analyser**. Such instrument is able to provide with information regarding the status of the line downstream the voltage stabiliser such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

The logic control is based on a microprocessor.

ARIES

Every ORION Y stabiliser can be transformed into an ARIES line conditioner by adding a set of components and an isolating transformer.

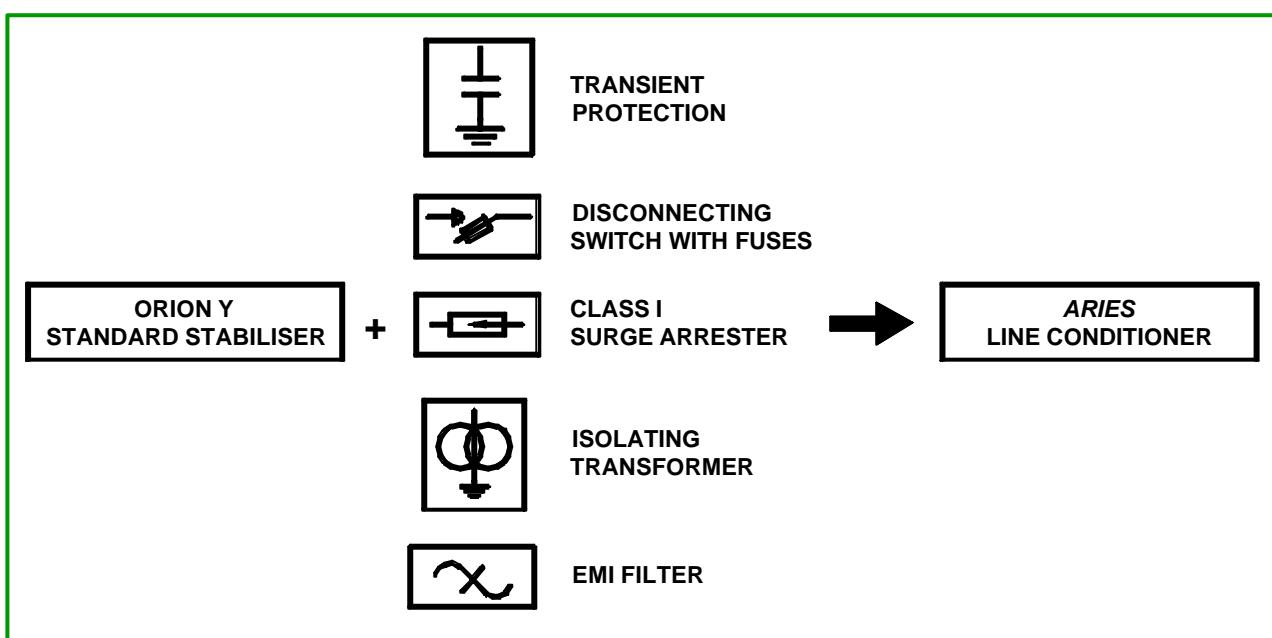

All ARIES are three-phase and cover the power rating range between 2kVA and 450kVA, allowing for the choice of several input voltage variation percentages.

The ARIES are available with independent regulation only.

Being the line conditioner provided with transient protection, disconnecting switch with fuses, surge protective devices, isolating transformer and EMI filter, a higher level of protection for the user is assured.

The measuring instrumentation for ARIES is mounted on the cabinet door and consists of a **multi-task digital network analyser**. Such instrument is able to provide with information regarding the status of the line downstream the voltage stabiliser, such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

The logic control is based on a microprocessor.

DISCOVERY

Every SIRIUS stabilisers can be transformed into a DISCOVERY line conditioner by adding a set of components and an isolating transformer.

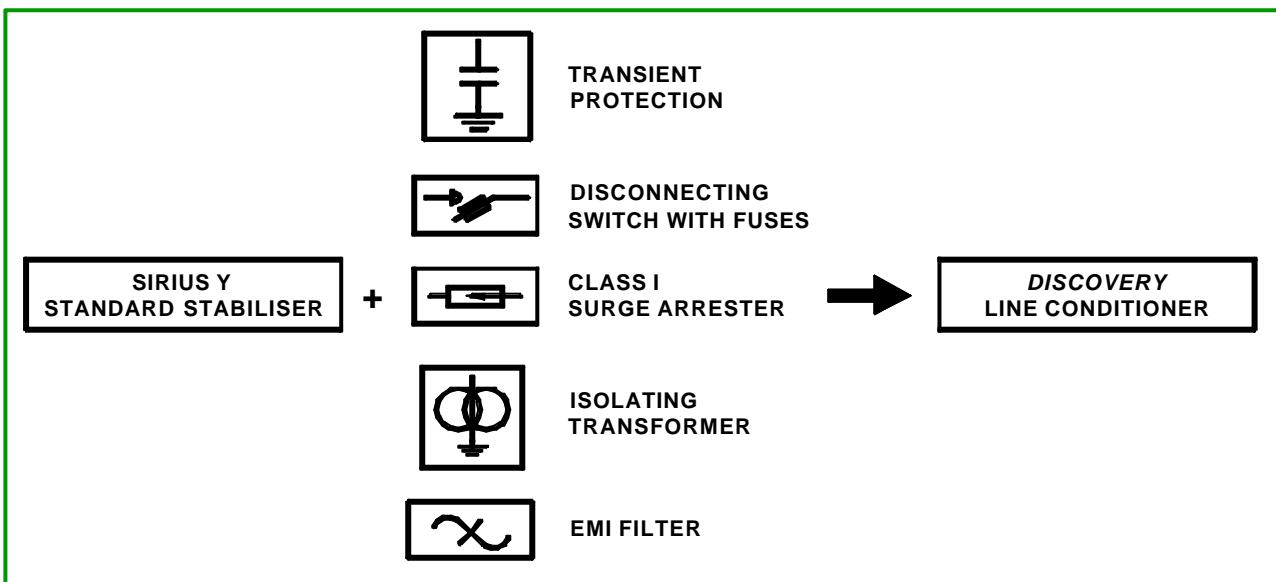

The DISCOVERY line conditioners are three-phase and cover the power rating range between 30kVA and 2000kVA, allowing for the choice of several input voltage variation percentages.

The DISCOVERY line conditioner is available with independent regulation on each phase only.

Being the line conditioner provided with transient protection, disconnecting switch with fuses, surge protective devices, isolating transformer and EMI filter, a higher level of protection for the user is assured.

The measuring instrumentation for the ARIES stabilisers is incorporated in a control panel on the cabinet door and consists of **two multi-task network analysers**. Such instruments are able to provide with information regarding the status of the lines upstream and downstream the voltage stabiliser such as phase and linked voltages, current, power factor, active power, apparent power, reactive power, etc.

The logic control, performed on the true rms voltage, is based on a 2-way microprocessor. By using this device, monitoring the system and setting the stabiliser parameters via a PC connection are made possible.

Input output voltage 50Hz: 380/415V - Input output voltage 60Hz: 460/480V

STATIC VOLTAGE STABILISERS WITH DIGITAL CONTROL

DESCRIPTION OF THE UNIT

This type of stabiliser finds application when the speed of operation is a critical issue (for example, computers, laboratory apparatus, measuring benches and medical instrumentation).

The response time is 2ms/V.

The stabilising system is designed to operate with rated voltage in accordance with IEC 38 and is expected to be connected between main power supply and load. However it is also designed so that it can operate with a different rated voltage (220V and 240V for single-phase; 380V and 415V for three phase) to be selected as necessary. The purpose is to supply the load a stabilised voltage having an input voltage variable with respect to the rated value. The stabiliser operates with a load variation range for each phase from 0 to 100% and is not affected by the power factor of the load; the harmonic distortion introduced on the output voltage is negligible. The presence of a RFI filter reduces the effect of mains interference on the load and likewise interference of the load towards the mains.

The voltage stabiliser does not provide galvanic separation between input and output.

The equipment is usually housed in a metal enclosure with RAL 7035 finish and IP21 protection degree, suitably sized according to the power rating.

MAIN COMPONENTS

The main components of the voltage stabiliser are:

- Multi-tap transformer;
- Microprocessor control system
- Set of **TRIAC** switches for GEMINI and AQUARIUS; Set of **IGBT** electronic switches for ODYSSEY
- Display

The autotransformer (single- or three-phase) is provided with taps to be connected to the voltage stabiliser output in order to be able to compensate for variations in the input voltage.

The microprocessor system monitors the input voltage and decides which transformer tap requires connection to the voltage stabiliser output in order to guarantee the best regulation of the voltage to the load.

The electronic switches, controlled by the microprocessor, run the connection of the transformer taps to the output when the alternating current crosses the zero-point.

The display system, controlled by the microprocessor, shows not only the load level, but also any input voltage outside the regulation limits as well as overload state and over temperature. An acoustic alarm is available for signalling overload and overheating.

GEMINI

The GEMINI single-phase voltage stabiliser is able to adjust the output voltage within $\pm 3\%$ of the rated voltage. The supplied load is protected both from $-18\% / +14\%$ variations of the input voltage and short but high overvoltages (4kV).

The main characteristics of the GEMINI electronic voltage stabilisers can be summarised as follows:

- Reliable operation thanks to a microprocessor full control
- Compact size
- Quick response time
- High efficiency
- Insensitivity to load power factor
- Wide range of information available via the front LED panel

Information available:

- Mains input voltage exceeding regulation limits
- Mains frequency exceeding limit
- Load lower than 25%, 50%, 75%, 100%
- Overload
- Alarm for input overvoltage and/or overheating (the visual alarm is accompanied by an acoustic alarm)

The logic control is based on a microprocessor.

Input output voltage 50Hz: 220/240V – Input/Output voltage 60Hz: 208/240V

AQUARIUS

The AQUARIUS three-phase electronic voltage stabiliser is able to adjust the output voltage within $\pm 3\%$ of the rated voltage.

The supplied load is protected both from $-18/+14\%$ ($-21/+14\%$ on request) variations of the input voltage and short but high overvoltages (4kV).

Voltage stabilisation is performed independently on each phase.

The main characteristics of the AQUARIUS electronic voltage stabilisers can be summarised as follows:

- Reliable operation thanks to a microprocessor full control
- Compact size
- Quick response time
- High efficiency
- Insensitivity to load power factor
- Wide range of information available via the front LED panel

Information available

- Mains input voltage exceeding regulation limits
- Mains frequency exceeding limit
- Load lower than 25%, 50%, 75%, 100%
- Overload
- Alarm for input overvoltage and/or overheating (the visual alarm is accompanied by an acoustic alarm)

The logic control is based on a microprocessor.

ODYSSEY

The ODYSSEY Electronic stabiliser is designed to supply a 400V voltage stabilised within $\pm 2\%$ to the load, working with a variable input voltage (with regard to the rated voltage value). The system is based on **IGBT** static switches and a single buck/boost transformer. Choosing the **IGBT** controlled regulation allows for a very fast response time (0.75msec/V). Thanks to a specially designed three-phase buck/boost transformer, the ODYSSEY stabiliser contains only one power magnetic part which means limiting weight and dimensions of the equipment. The ODYSSEY is housed in an IP21 metallic cubicle provided with front door thus allowing for easy access to the components. The **IGBT** switches and the other semiconductors are protected against overvoltages and overcurrents due to short-circuits either on the mains or on the plant. Such protection is obtained by means of auxiliary circuits integrated in the logic control. In addition, a thyristor based by-pass circuit is provided. The circuit activates in case of overload or logic control failure. The heart of the stabiliser is the Electronic Control Unit that manages the three phases independently by means of three control cards and an alarm card. In order to ease inspection and maintenance, all the boards are Eurocard type thus providing with removable and interchangeable components. Each phase card gives indications concerning supply presence, regulation mode and regulation limits. The alarm card deals with abnormal conditions and warns the operator about a possible problem by means of a red led and a siren (that can be silenced).

All the electrical data are shown on the display of a versatile digital multimeter. The relevant values can be easily read and transferred onto a remote PC thanks to the foreseen RS485 output, an interface and a dedicated software.

The logic control is based on a microprocessor.

The main features of the ODYSSEY stabiliser are:

- Modular system (rating up to 1MVA)
- Fast response time
- Independent regulation on each phase
- Automatic input circuit breaker
- Absence of moving parts
- Protecting by-pass on the **IGBT**
- Negligible harmonic distortion
- 100% phase unbalance allowed
- 0 to 100% load variation allowed
- Remote control software
- Surge protective devices against lightning and/or spike reduction varistors
- RFI and EMI filters
- Not affected by the load power factor

The following accessories can be included on request:

- By-pass line (manual or automatic)
- Isolating input transformer to reduce line noise and transients and protect from lightnings
- Output interrupting devices
- Other auxiliary circuits or signals

ODYSSEY STANDARD FEATURES

| | |
|-------------------------------------|---|
| FREQUENCY | 48/63Hz |
| ADMITTED LOAD VARIATION | from 0 to 100% |
| ADMITTED LOAD UNBALANCE | Up to 100% |
| MAINS WAVEFORM DISTORTION INCREMENT | < 0.2% |
| COOLING | Natural Ventilation (Aided ventilation over 40°C) |
| AMBIENT TEMPERATURE | -15/+45 °C |
| STORAGE TEMPERATURE | -25/+60°C |
| RELATIVE HUMIDITY | 90% |
| ADMITTED OVERLOAD | 200% 2sec |
| COLOUR | RAL 7032 |
| PROTECTION | IP 21 |
| INSTALLATION | Indoor |

ACCESSORIES

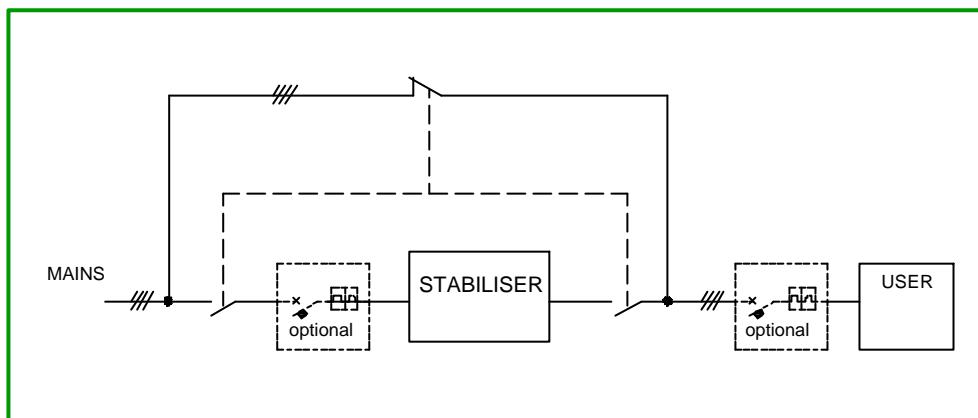

The characteristics described so far are typical of the standard machine. Accessories performing other tasks can be supplied on request. Combinations of one or more of the following accessories are usually installed in an additional modular enclosure.

1. By-pass switch

Useful for working on the voltage stabiliser without switching off the power supply to the loads. For the operators' safety, the by-pass operation should be manual. The by-pass device consists of three interlocked switches with three positions

- by-pass OFF/stabiliser ON
- by-pass OFF/stabiliser OFF
- by-pass ON/stabiliser OFF

The circuit can include automatic circuit breakers.

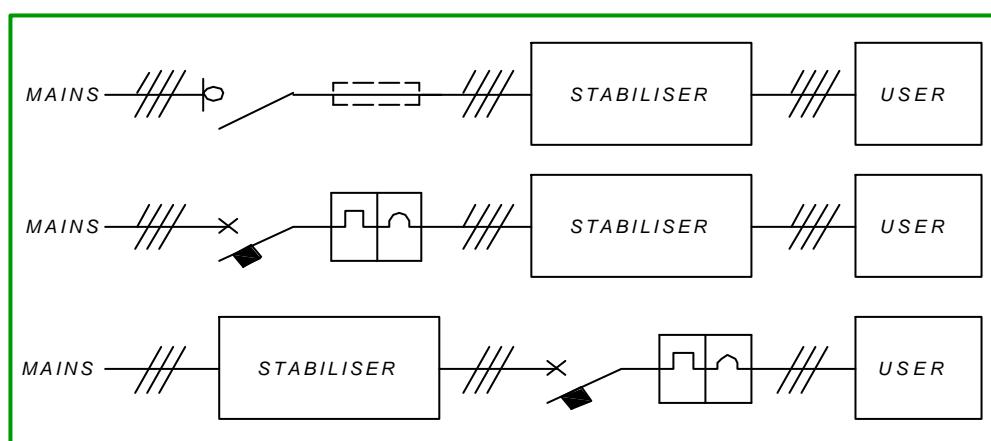

2. Input isolation transformer

It provides for galvanic separation between the stabiliser with its load and the mains.

It also protects from possible overvoltages.

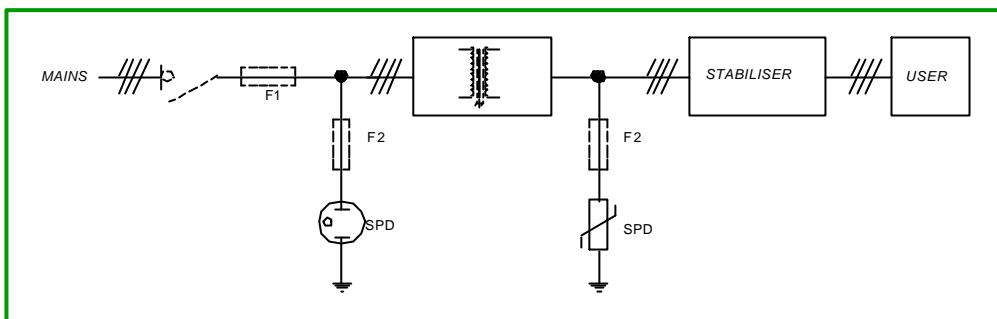

3. Interrupting devices

Fused disconnections or circuit breakers with thermal and magnetic release can be supplied whenever it is necessary to isolate the input line, the output one or both.

4. Surge arresters (SPD)

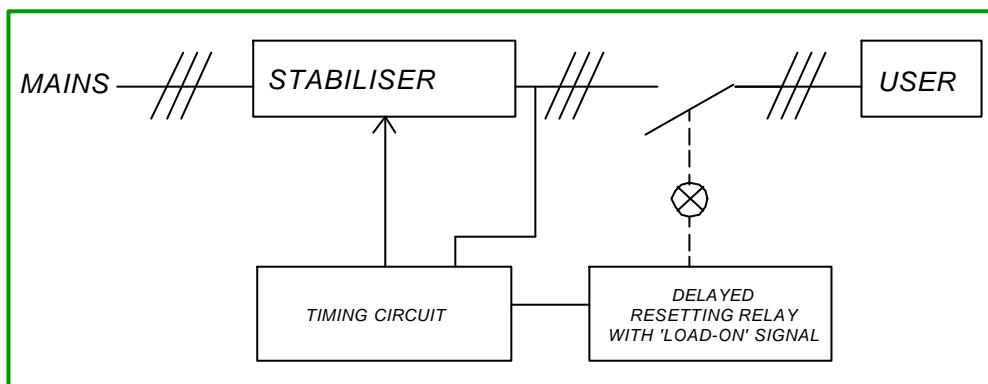

Surge arresters (lightning arresters) and overvoltage suppressors can be provided to protect from overvoltage peaks of atmospheric or operational origin by discharging them to ground. The installation depends on the system configuration. For example, in case of high ratings the suggested sequence would be: spark-gap arresters followed by an isolating device (ideally an isolating transformer) and varistor-based arresters on its output.

5. "Soft Start" Circuit

The 'Soft Start' circuit is a protection with a double purpose:

- To delay the connection to the load each time the stabiliser switches on so that the users can undergo a smooth start-up with an already stabilised voltage.
- To protect the load from surges, sags and overload by disconnecting the load from the stabiliser.

6. Protection degree (IP)

High protection degree (until IP54) can be obtain increasing the dimensions or with heat exchanger and air condition.

7. Additional instrumentation and special construction

For special requirements, the instrumentation can be expanded according to request, with provision for computerised remote signalling.

Due to our flexibility, it is possible to customise the design according to specific requests.

8. Outdoor constructions

On request the stabiliser can be designed for outdoor construction with stainless steel or glass-fibre cabinet.

"CUSTOMISED" CONSTRUCTIONS

The production of stabilisers is completed by special constructions items based on the Customer's specifications. These machines can include:

- Open-type stabilisers that are widely used inside UPS systems, generating sets, etc
- Stabilisers designed to be assembled inside a cabinet provided by the Customer
- Stabilisers designed for cabinets with high level of IP protection (outdoor installation, dusty environment, etc.)

All the before mentioned types of stabilisers can be used in order to build a special construction.

Some examples are shown in the following photographs.

VOLTAGE REGULATOR SYSTEM

Assembly of full systems for voltage regulation is a direct offshoot of the production of voltage regulators. Typical applications of voltage regulators consist of test benches, variable load supply systems and electric furnaces. The equipment is assembled inside a metal cabinet of size suitable for the rated power of the system or else it is mounted on an open frame.

Regulation of the output voltage is through electromechanical components. Operation is motorised and is activated by push buttons mounted on a control panel installed in the electrical cabinet or else remote control is provided. The voltage regulator is normally used as a component of a wider system. Therefore protective devices should be mounted before and after the unit rated according to the currents circulating.

The unit is normally air cooled. However for very high power ratings, the voltage regulator and/or power transformer is placed inside tanks and oil cooled. The voltage regulation system is normally connected directly to the mains. On request, an input isolation transformer can be installed in order to have galvanic separation before the equipment.

DRY TYPE MV TRANSFORMERS

The dry type MV transformers cover the power rating range between 160kVA up to 3150kVA and are normally installed in areas close to where people live and work. Therefore safety, fire hazards and environmental problems are important factors.

Dry-type transformers often quite rightly called "ecological", provide the solution to this type of problems. In fact, in case of fire, they have minimum combustion capability and do not release additional toxic gases. They are suitable for installation in environments with high humidity and chemically aggressive atmospheres. Moreover they are resistant to thermal shock and therefore able to operate even at very low temperatures (-40°C). Such transformers do not require preventive maintenance, therefore routine maintenance is minimum. Furthermore the polyester insulation means that the copper can be recycled after decommissioning.

ACCESSORIES

Standard:

- Load-bearing resin insulators on high voltage side
- Connections for the ±2x2.5% variation on the high voltage side
- Copper plates for connection on low voltage side
- Eye-bolts for hoisting the transformer
- Bi-directional wheels
- Earth (ground) terminals
- Nameplate
- Temperature probes with connection terminals

On request:

- Electronic instrument connected to the temperature probes with temperature indication on LCD display and setting of overtemperature alarms
- Cabinet with IP20, IP21, IP23 protection class
- Vibration-damping pads for handling with transpallets
- Forced air cooling system with radial or axial fans, with or without cabinet

EPOXY RESIN MV TRANSFORMERS

Epoxy resin transformers offer the highest level of safety against fire while they safeguard the environment. They do not require maintenance and they are designed for easy installation (they avoid the need for construction of fire-fighting equipment and/or oil collecting ditches).

Advantages offered by choosing a transformer of this type can be summed up as follows:

- High level of safety and environment friendly
- Easier installation
- Minimum maintenance
- Flame retardant with excellent fire resistance
- High decomposition temperature without appreciable toxic emission in the case of fire
- Suitable for environments with high dust loading and/or with chemically aggressive atmosphere
- High degree of insulation and no partial discharges
- Very low losses
- Good resistance to impulse overvoltage and to short circuits for all power rating and voltage ranges

ACCESSORIES

Standard:

- Load-bearing resin insulators on high voltage side
- Connections for the $\pm 2 \times 2.5\%$ variation on the high voltage side
- Copper plates for connection on low voltage side
- Eye-bolts for hoisting the transformer
- Bi-directional wheels
- Earth (ground) terminals
- Nameplate
- Temperature probes with connection terminals

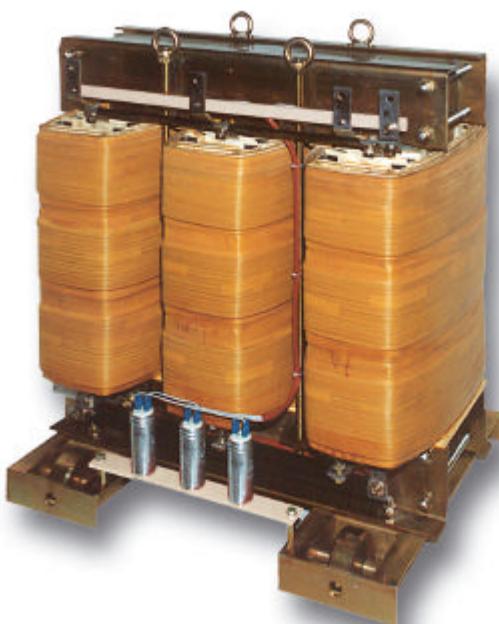

On request:

- Electronic instrument connected to the temperature probes with temperature indication on LCD display and setting of overtemperature alarms
- Cabinet with IP20, IP21, IP23 protection class
- Vibration-damping pads for handling with transpallets
- Forced air cooling system with radial or axial fans, with or without cabinet

LV TRANSFORMERS

The range of LV single-phase transformers covers the power rating between from 50kVA up to 1000kVA, the three-phase from 100kVA up to 2000kVA. These transformer find very wide application: from supplying systems, rectifier circuits, inverters, uninterruptible power supplies (UPS) to electro-plating, furnaces, or else merely as separators between the main power supply and users. They are normally built according to application requirements, thus allowing great flexibility in choosing nominal parameters, ratings and sizes. Although normally designed for open version, the transformer can be supplied housed in a metal cabinet.

Three phase high insulation transformer (20kV)

Three-phase five-legs transformer

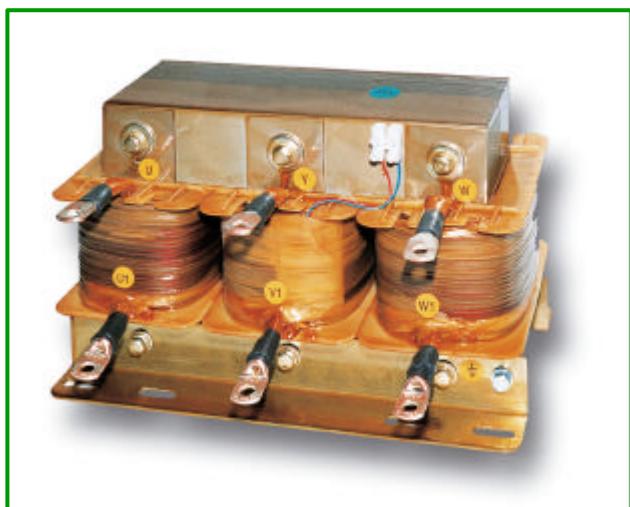

MV/LV REACTORS

ORTEA has been manufacturing reactors for many years. Thanks to an extensive experience and strong co-operation with the customers, a specific know-how of the problems and various applications regarding such equipment has been built up.

Each type can be manufactured for low voltage and medium voltage with insulation level up to 36 kV. Construction is in compliance with the relevant Technical Standard (EN 60289).

The ORTEA production of reactors covers the entire field of applications: medium voltage insertion reactors; medium voltage choking inductors; tuning reactors; blocking reactors; current limiting reactors; smoothing inductors; special reactors. The reactors are built according to application requirements, thus allowing wide flexibility in choice of nominal parameters, ratings and size.

The standard MV reactors range is for electrical insulation class for 17.5kV, however other insulation classes can be obtained, namely: 3.6kV, 7.2kV, 12kV, 24kV e 36kV.
